PCT/CH99/00452

Screw-type intraosseous dental implant

Field of application of the invention

The present invention relates to a dental implant which
 5 is intended to be fitted in the jawbone and which has a
 thread on its outside. To this extent, the implant
 according to the invention differs generically from
 blade and cylinder implants as the other forms of
 intraosseous dental implants. In particular, the
 10 invention concerns the outer geometry of the implant,
 the measurement ratios of the implant body, and the
 characteristics of the outer thread, with the object of
 improving both primary and secondary stability and of
 thereby guaranteeing the long-term success of fitted
 15 implants.

Prior art

Although this invention concerns dental implants, the
 shorter form "implant" will be used hereinafter for the
 20 sake of brevity. An overview of the implant forms
 commonly used in dentistry is given by H. Spiekermann
 in "Implantologie, Farbatlanten der Zahnmedizin"
 published by Georg Thieme Verlag Stuttgart and New
 York, 1994, vol. 10, page 15. Here, a differentiation
 25 is made between blade, cylinder and screw implants. The
 blade implants which may possibly be advantageous for
 very specific applications are not considered at all.
 The cylinder implants have a cylindrical body which is
 either continuous or stepped. The root part can have
 30 openings for better bone integration, and the implant
 tip lying at the apical end has the shape of a
 semisphere or a rounded summit. The root part has a
 rough or profiled surface produced by material
 application or removal. The implant neck or head is in
 35 most cases smooth.

The screw implants have an outer thread extending at

204428001-031402

least over most of the root part. Their implant bodies are likewise cylindrical with a semispherical, rounded, frustoconical or parabolic implant tip (see US 4,626,214). Slightly conical forms are also known (see
5 US 4,713,003). The implant necks are in most cases also cylindrical at the transition from the root part, whereas in the coronal direction the heads taper conically, widen in a trumpet shape or have an external polygon.

10 The basically cylindrical shape of the root part has proven not best suited for obtaining the desired postoperative primary stability of the fitted implant. Moreover, the lifetime of the implants is in many cases
15 inadequate: the fitted implant loosens early after just a few years. Investigations revealed that this early loosening is caused by bone resorption around the fitted implant, which is attributable to insufficient introduction of force to the bone via the existing
20 implant forms. Bone expansions of between 1000 and 4000 microstrains are defined as relevant to remodeling. Values below 1000 microstrains are considered inadequate and result in reduced mineralization and formation of connective tissue. Values above 4000
25 microstrains are considered excessive and result in bone resorption (see Barbier, L. et al.: Finite element analysis of nonaxial versus axial loading of oral implants in the mandible of the dog, in J. Oral Rehabil. 1998, 25(11):847-858).

30

Object of the invention

In view of these shortcomings of the dental implants known to date, it is an object of the invention to propose an implant form which contributes to increasing
35 the primary stability of fitted implants so that the implant is immediately able to bear loads, both during the postoperative work involved in attaching the superstructures and also during use by the patient.

10088001.031402

Immediate ability to bear loads signifies the primary stability achieved immediately after implantation. However, it will be appreciated that in some cases it is advantageous to wait several days of the main wound-healing phase before actual loading of the implant. Moreover, an optimized implant form is intended to maintain the natural introduction of force into the bone, comparable to that in a real tooth, and thereby to guarantee the long-term success to a greater extent.

10

Summary of the invention

The dental implant has a bottommost implant tip located at the apex and a root part which extends to the implant tip and is intended to be fitted in the jawbone. Adjoining the root part there is the implant neck which extends in the coronal direction and, in the implanted state, comes to lie inside the gingiva. At least over some of the root part, the implant is provided with an outer thread, which can be self-cutting. The main feature is that the root part has a principally parabolic outer contour with the implant tip as vertex.

20

The description given below relates to preferred illustrative embodiments of the invention.

25

The root part and the implant neck adjoin each other on a theoretical ridge line, the root part having the maximum length l_{\max} extending in the axial y-direction. At the ridge line, the root part has the maximum radius r_{\max} extending in the radial x-direction. Placed in a cartesian system of x-y coordinates, and with the implant tip positioned at the origin of this system, the parabolic outer contour follows the equation

30

35

$$l_y = K \cdot 4r_x^2, \text{ with:}$$

l_y as the respective ordinate value;

r_x as the associated abscissa value; and

K as the constant resulting from the equation

10088001-031402

$$K = l_{\max} : 4r_{\max}^2.$$

10088001-031402
The maximum radius r_{\max} is between 1.0 mm and 3.0 mm; it
5 preferably lies in the range of from 1.5 mm to 2.0 mm.
The maximum length l_{\max} of the root part correlates
with the pitch of the outer thread, the latter ending
at a distance from the ridge line. The distance is
preferably 1.0 mm to 4.0 mm. This distance is defined
10 by the thickness of the cortical zone on the marginal
bone and by the length of the implant. In order to
guarantee an optimum introduction of force into the
bone in this area, the distance of the outer thread
from the ridge line becomes greater as the length of
15 the root increases. In addition, the distance
contributes to excluding the very critical entry of
bacteria into the implant bed.

20 At the root part, and extending in the y-direction, the
thread teeth have a height in the region of 0.3 mm;
and, extending in the x-direction, a length in the
range of from 0.25 mm to 0.5 mm. The length of the
thread teeth decreases as the maximum length of the
root part increases.

25 The implant is made of biocompatible material having
suitable stability properties. Examples of these are
titanium, titanium-based alloys, other metals or metal
alloys, ceramic, glass ceramic or ceramic-like
30 materials, and biocompatible plastics. The root part
has a rough surface which is, for example, plasma-
coated or ceramic-coated, or has been treated, for
example, chemically, electrochemically, mechanically or
by laser. An implant neck made of titanium or a
35 titanium-based alloy is polished. The implant neck can
also be coated with ceramic or with ceramic-like
material or with hydroxyapatite. Measured in the y-
direction, the implant neck has a height in the region

of 2.0 mm and is cylindrical or widened or narrowed in a trumpet shape or conically in the coronal direction. The dental implant can be used either as a one-phase or two-phase implant.

5 Brief description of the attached drawings

Figure 1 shows a front view of an implant according to the invention;

Figure 2 shows the implant according to Figure 1 in a system of x-y coordinates; and

10 Figure 3 shows an enlargement of the detail X from Figure 1.

Embodiment

15 There follows a detailed description of an illustrative embodiment of the dental implant according to the invention, with reference to the attached drawings.

At the very bottom of the implant is the apically situated implant tip 1 to which the root part 2 extends from the coronal direction, which root part 2 is intended to be fitted in the jawbone. Adjoining the top of the root part 2, at the theoretical ridge line 5, is the implant neck 3 which extends in the coronal direction and is intended to lie inside the gingiva.

20 From the implant tip 1 to a point below the ridge line 5, the root part 2 is provided with an outer thread 4 which is preferably self-cutting and has the pitch S. The outer thread 4 ends at a distance below the ridge line 5; the distance is preferably in the range of from

25 1.0 mm to 4.0 mm. The root part 2 has a substantially parabolic outer contour A with the implant tip 1 as vertex.

30

The following dimensions can be defined on the implant:

35 1 → total length, for example 12.0 mm, extending in the axial y-direction, on the ordinate axis;

l_{\max} → part of the total length 1 and maximum length of the root part 2;

- h → part of the total length l and height of the
implant neck 3;
 r_{\max} → maximum radius of the root part 2 at the ridge
line 5, extending in the radial x-direction, on
the abscissa axis;
d → nominal diameter of the implant, which is derived
from $2 \cdot r_{\max}$;
 g_h → height of the thread teeth 40 of the outer thread
4 on the root part 2, extending in the y-
direction;
 g_1 → length of the thread teeth 40 in the x- direction.

If the implant is placed with its parabolic outer
contour A in a cartesian system of x-y coordinates and
the implant tip 1 is positioned in this case at the
origin of the system of coordinates, the outer contour
A follows the equation $l_y = K \cdot 4r_x^2$. Here represent:

- l_y → the respective ordinate value for forming the
outer contour A;
 r_x → the abscissa value associated with the ordinate
value l_y , and
K → the constant which results from the equation
 $K = l_{\max} : 4r_{\max}^2$.

The maximum radius r_{\max} is between 1.0 mm and 3.0 mm,
preferably lying in the range of from 1.5 mm to 2.0 mm.
Thus, assuming for example that $r_{\max} = 2.0$ mm (nominal
diameter of the implant $d = 4.0$ mm), this gives the
following values for the constant K and for the
equations for determining the ordinate values l_y and
abscissa values r_x of the outer contour A:

Length l_{\max} of root part [mm]	$l_y ; r_x$	Constant K
6	$l_y = K \cdot 4r_x^2$	0.375
8	$l_y = K \cdot 4r_x^2$	0.500
10	$l_y = K \cdot 4r_x^2$	0.625
12	$l_y = K \cdot 4r_x^2$	0.750
14	$l_y = K \cdot 4r_x^2$	0.875

16	$l_y = K \cdot 4r_x^2$	1.000
----	------------------------	-------

The maximum length l_{\max} of the root part 2 correlates with the pitch S of the outer thread (4).

- 5 Thus, assuming for example that $r_{\max} = 2.0$ mm (nominal diameter of the implant $d = 4.0$ mm) and assuming maximum lengths l_{\max} , this gives the following relations for the pitch (S) of the outer thread 4:

Length l_{\max} of root part [mm]	Pitch (S) [mm]
6	0.65
8	1.00
10	1.00
14	1.00
16	1.00

10

The outer thread (4) at the root part (2) with its thread teeth (40) has the following values, for example:

- 15
- extending in the y -direction, a height g_h of the thread teeth 40 in the region of 0.3 mm; and
 - extending in the x -direction, a length g_1 of the thread teeth 40 in the range of from 0.25 mm to 0.5 mm.

- 20 The length g_1 of the thread teeth 40 decreases as the maximum length l_{\max} of the root part 2 increases.

- 25 Thus, assuming for example $r_{\max} = 2.0$ mm (nominal diameter of the implant $d = 4.0$ mm), this gives the following values for the outer thread 4 with its thread teeth 40:

Length l_{\max} of root part [mm]	Height g_h of thread teeth [mm]	Length g_1 of thread teeth [mm]
6	0.30	0.40

10088001 "031402

8	0.30	0.40
10	0.30	0.30
14	0.30	0.25
16	0.30	0.25

10088001.031402

The implant is made of biocompatible material having suitable stability properties. Examples are titanium, titanium-based alloys, other metals, their alloys, ceramic, glass ceramic or ceramic-like materials, and biocompatible plastics. The root part 2 has a rough surface which, for example, is plasma-coated or ceramic-coated or is treated, for example, chemically, electrochemically, mechanically or by laser. An advantageous surface structure for the root part 2 is the subject of the invention in PCT publication WO 99/13700. The implant neck 3 can be made of titanium, a titanium-based alloy, another biocompatible metal or alloy and will then advantageously be polished. The implant neck 3 could be coated with ceramic, glass ceramic, ceramic-like material, hydroxyapatite, plastic or metal.

The implant neck 3 has, in the y-direction, a height h in the region of, for example, 2.0 mm. It is cylindrical or widens or narrows in a trumpet shape or conically in the coronal direction.
